

Illumination

Total light decomposition

$$\text{Light} = \text{reflected} + \text{transmitted} + \text{absorbed}$$

Reflected light

$$\text{Reflected light} = \text{ambient} + \text{diffuse} + \text{specular}$$

$$I = I_a + I_d + I_s$$

Illumination - Examples

ambient

ambient + diffuse

ambient + diffuse + specular
(and a checkerboard)

Ambient Reflection

- Uniform background light
- $I_a = k_a I_A$
 - I_A : ambient light
 - k_a : material's ambient reflection coefficient
- Models general level of brightness in the scene
- Accounts for light effects that are difficult to compute (secondary diffuse reflections, etc)
- Constant for all surfaces of a particular object and the directions it is viewed at

Diffuse Reflection

- Models dullness, roughness of a surface
- Equal light scattering in all directions
- For example, chalk is a diffuse reflector

$$L = \frac{Light - P}{|Light - P|} = \frac{(Light_x - P_x)}{|L'|}, \frac{(Light_y - P_y)}{|L'|}, \frac{(Light_z - P_z)}{|L'|}$$

$$|L'| = \sqrt{(Light_x - P_x)^2 + (Light_y - P_y)^2 + (Light_z - P_z)^2}$$

Dot product:

$$N \cdot L = (N_x L_x + N_y L_y + N_z L_z)$$

Lambertian cosine law:

$$I_d = k_d I_L \cos \varphi = k_d I_L N \cdot L$$

I_L : intensity of lightsource

N : surface normal vector

L : light vector (unit length)

φ : angle of light incidence

k_d : diffuse reflection coefficient
(material constant)

Note: $I_d = 0$ for $N \cdot L < 0$

Specular Reflection - Fundamentals

- Models reflections on shiny surfaces (polished metal, chrome, plastics, etc.)
- Ideal specular reflector (perfect mirror) reflects light only along reflection vector R
- Non-ideal reflectors reflect light in a lobe centered about R
 - $\cos(\alpha)$ models this lobe effect
 - the width of the lobe is modeled by Phong exponent ns , it scales $\cos(\alpha)$

Phong specular reflection model:

$$I_s = k_s I_L \cos^{ns} \alpha = k_s I_L (E \cdot R)^{ns}$$

I_L : intensity of lightsource

L : light vector

R : reflection vector = $2 N (N \cdot L) - L$

E : eye vector = $(\text{Eye} - P) / |\text{Eye} - P|$

α : angle between E and R

ns : Phong exponent

k_s : specular reflection coefficient

Specular and Diffuse Reflection - Varying the Coefficients

diffuse coefficient k_d

Phong exponent n_s

Specular Reflection - Using the Half Vector

- Sometimes the half vector H is used instead of R in specular lighting calculation
- Both alternatives have similar effects

Phong specular reflection model:

$$I_s = k_s I_L \cos^{ns} \beta = k_s I_L (H \cdot N)^{ns}$$

I_L : intensity of lightsource

L : light vector

H : half vector = $(L + E) / |L + E|$

R : reflection vector

E : eye vector

Total Reflected Light

- Total reflected light (for a white object):

$$I = k_a I_A + k_d I_L N \cdot L + k_s I_L (H \cdot N)^{ns}$$

- Multiple lightsources:

$$I = k_a I_A + \sum (k_d I_i N \cdot L_i + k_s I_i (H_i \cdot N)^{ns})$$

- Usually, I is a color vector of (R=red, G=green, B=blue)
- Object has a color vector $C_{obj} = (R_{obj}, G_{obj}, B_{obj})$
- Object reflects I , modulated by C_{obj}
- Color C reflected by object:

$$C = C_{obj} (k_a I_A + \sum (k_d I_i N \cdot L_i)) + \sum (k_s I_i (H_i \cdot N)^{ns})$$

- In many applications, the specular color is not modulated by object color
 - specular highlight has the color of the lightsource
- Note: (R, G, B) cannot be larger than 1.0 (later scaled to [0, 255] for display)
 - either set a maximum for each individual term or clamp final colors to 1.0
